I had the most difficulty with checking the data object from my request and getting my console.logs to appear in the browser debug panel. Initially, I accidentally added the weather API request call inside the GET request, resulting in the same task being added over and over to my to do app. Then I moved it over to the POST request but the data from the request simply showed up as the string "Weather." I suspected there was a more complex response. So I tried to console.log. I think that the browser is doing a refresh wiping out the logs.

After some debugging work, I was able to resolve this issue by realizing that in server side code the logs are happening in the terminal. I soon recalled (by way of a Google search) that a 401 error means I am unauthorized to access the resource. So I went on a quest to find the correct key to hit that endpoint. I also realized that debugging is quite expedited if I move the code I am changing to a GET request or if I simply make the calls from the terminal with a curl request. All in all a fun exercise on paying attention.
